## Detailed Description Text - DETX (119):

With a sharp knife, the surgeons cut into the coronary artery (arteriotomy). The arteriotomy is then increased to 8 to 12 mm with Pott's or reversed acute angle scissors. The internal diameter of the coronary artery is calibrated at the size recorded. The distal part of the graft that has been set aside is sewn to the coronary artery with the same fine sutures that are used in standard bypass operations (FIG. 41). A continuous suture of 6-0 or 7-0 Prolene is begun in the heel of the vein graft with a narrow mattress stitch and continued to the proximal portion of the coronary artery. Approximately 1-mm bites are taken as the suture line is continued around one side to the distal end. At that point the suture line may be interrupted with one or more sutures. With smaller vessels interrupted sutures are easy to insert and less likely to constrict the anastomosis. With larger vessels (2.5 mm or greater) the suture line may be continued without interruption around the distal end. The other end of the original stitch is continued on the contralateral side, and the anastomosis is terminated at the midpoint of the arteriotomy. Anastomotic patency is checked in both directions. A flush of clear solution through the needle may be of aid during the performance of the distal anastomosis to keep the anastomotic area free of blood. Alternatively, the coronary artery and bypass vein grafts can be anastomosed by applying tissue adhesive (glue) between their adjacent outer walls, without using sutures, which facilitates and expedites the coronary anastomosis when application of tissue adhesive make two structures bonded in a side-to-side fashion, a fenestration in a proper length is made between them by putting an incision extending from the lumen of vein graft to the lumen of the coronary artery with a knife inserted via the distal open end of the graft. After this, the open distal end of the vein graft is sewn as a blind end.

TITLE: Apparatus and method for engrafting a blood vessel

----- KWIC -----

## Brief Summary Text - BSTX (28):

In a preferred embodiment, the graft apparatus further comprises a plurality of outer packets formed of a light degradable polymer and containing a tissue adhesive which is released by fiber-optic scope after the graft is implanted to bond the ends of the graft to the interior surface of the vessel and prevent leakage through micro-cracks therebetween. Medical grade expandable foam cuffs preferably surround the middle portion of the graft to promote clotting within the aneurysm sac. Alternatively, light actuated cryo precipitate fibrin glue may be painted onto the exterior surface of the graft material with a brush. The adhesive naturally remains as syrup until light actuates and cures. This replaces the need for packets and reduces the possibility of premature release of adhesive from packets that may break during deployment.

## Brief Summary Text - BSTX (36):

Once the graft is correctly deployed, the deployment means may be completely withdrawn from the patient, and a fiber-optic scope inserted through the entry site to direct light at the tissue adhesive packets to cause the packet polymer material to degrade, thereby releasing the tissue adhesive. Finally, the entry site attended using standard procedure. Post-operative imaging may be conducted to verify isolation of the aneurysm, with particular attention being given to the occurrence of leaks at the proximal end of the graft closest to the heart.

## Detailed Description Text - DETX (6):

Graft 20 further includes a plurality of releasable tissue adhesive packets 56 fixed to an exterior surface of graft material 24 at ends 28 and 30 for establishing a fluid tight seal between graft material 24 and the inner wall of aorta 10. Packets 56 may be constructed of photosensitive polyurethane and filled with biocompatible tissue adhesive, for example fibrin glue or isobutyl 2 cyanoacrylate. The tissue adhesive remains secure during deployment, and may subsequently be released by directing a fiber-optic catheter light source at packets 56 from inside graft 20 to cause breakdown of the packet material. Tissue adhesive enters and occupies small micro-cracks existing between graft material 24 and the interior surface of aorta 10 to form a bonding fluid seal, thereby preventing the serious problem of leakage. An alternative to the described tissue adhesive packets is the use of light activated cryo precipitate fibrin glue painted on the exterior surface of the graft material.

fibres, such as glass fibres of 0.1-1 mm in length. Organic fillers which may in particular be listed are swellable powders and fibres having a fibre length of >0.01 mm, for example fibres based on polyacrylic acids and the salts thereof or others, as are for example stated in Absorbent Polymer Technology (Brannan-Peppas, Harland, Elsevier, Amsterdam-Oxford-New York-Tokyo, 1990, pp. 9-22), and materials used as textile fibres, such as for example polyester or polyamide fibres. Dyes or colouring pigments should in particular be taken to be those as may be used in foodstuffs, packaging or cosmetics. Liquid extenders or resins are in particular polymeric vinyl compounds, polyacrylates and other copolymers conventional in adhesives technology, which may have an influence upon adhesion properties.

**Brief Summary Text - BSTX (33):**

The ~~polyurethane~~ gel compositions and ~~polyurethane~~ foam gel compositions according to the invention may generally be used for the production of mouldings and ~~adhesive~~ layers, in particular of products which come into contact with human and animal tissues, such as with the skin, with mucous membranes or with open wounds or body fluids or secretions, such as for example saliva, blood, wound fluids, urine, faeces or sweat. The materials are also suitable for sticking or attachment to the skin. Use in medical applications is preferred, in particular as weakly or strongly self-~~adhesive~~ coatings, used as sticking plasters, rapid wound dressings or for sticking wound care products onto the body's surface. They also act to absorb blood and wound secretions and to provide padding and thermal insulation. Absorption of liquids may be accelerated by foaming the gels according to the invention. A distinctly improved padding effect and improved thermal insulation are furthermore achieved. Further areas of application are orthopaedic articles, personal hygiene or cosmetic articles or highly moisture absorbing, swellable and cushioning overlays or inserts, optionally also as pressure-distributing filling compositions for cushions or padding elements.

**Detailed Description Text - DETX (23):**

2) A parts by weight (pbw) of the base polyol were combined with B pbw of anti-oxidant, C pbw of catalyst and optionally also E pbw of filler and homogenised for 2 hours at room temperature in a 5 litre stirring apparatus. Using a standard mixing and metering unit for processing ~~polyurethane~~ and adhesive preparations, Y pbw of this mixture were vigorously mixed with Z pbw of isocyanate 1 and optionally F pbw of the foaming agent.

TITLE: .alpha.-Cyanoacrylate compound, method of preparing same and adhesive comprising same

----- KWIC -----

## Detailed Description Text - DETX (19):

The novel .alpha.-cyanoacrylate compounds according to the present invention show a bonding performance to a substrate made of various kinds of material in the same manner as the known .alpha.-cyanoacrylate such as ethyl .alpha.-cyanoacrylate and are effectively used as fast setting adhesives. The adhesives comprising the novel .alpha.-cyanoacrylate compounds according to the present invention are odorless or slightly give out fragrance whereby being remarkably easy to handle in the preparing process and the bonding process, producing no whitening in the bonding process, and improving the polymerized set products in brittleness. In addition, they are superior to the conventional .alpha.-cyanoacrylate in bonding strength to various kinds of substrate, for example metals, plastics, rubber, glass, wood and the like, particularly plated articles. It is perhaps owing to the chelate effect. Furthermore, the adhesives comprising .alpha.-cyanoacrylate, in which R.sup.2 is allyl group (CH.sub.2 CH.cbd.CH.sub.2), of the novel .alpha.-cyanoacrylate compounds according to the present invention have such an advantage that the substrate bonded therewith does not show a large reduction in bonding strength even when kept in a long time under the high temperature condition (for example one month at 150.degree. C.). In addition, the adhesives according to the present invention are superior in bonding (i.e. joining, bleed-stopping) strength to tissues of living bodies such as skin, gum, blood vessel and various kinds of organ and absorptivity into tissues after bonding.

## Detailed Description Text - DETX (20):

Additives such as radical polymerization inhibitors, anion polymerization inhibitors, plasticizers, tackifiers, coloring agents, fillers, diluents, water, perfumes, carboxylic acids, carboxylic anhydrides and polyisocyanates may be added to the adhesives according to circumstances.

 TITLE: Prosthetic devices including elastin or elastin-based materials

----- KWIC -----

Brief Summary Text - BSTX (7):

Until relatively recently, the primary methods available for securing a prosthetic material to tissue (or tissue to tissue) involved the use of sutures or staples. Fibrin ~~glue~~, a fibrinogen polymer polymerized with thrombin, has also been used (primarily in Europe) as a ~~tissue~~ sealant and hemostatic agent.

Detailed Description Text - DETX (10):

Tissue welding techniques employing a soldering agent can be used. Such techniques are known (WO 91/04073). Any proteinaceous material that thermally denatures upon heating can be used as the soldering agent (for example, any serum protein such as albumin, fibronectin, Von Willebrand factor, vitronectin, or any mixture of proteins or peptides). Solders comprising thrombin polymerized fibrinogen are preferred, except where such materials would cause undesirable thrombosis or coagulation such as within vascular lumens. Solders are selected for their ability to impart greater ~~adhesive~~ strength between the biomaterial and the ~~tissue~~. The solder should be non-toxic and generally biocompatible.

 TITLE: Anterior segment coronary restoration apparatus and method

----- KWIC -----

Detailed Description Text - DETX (48):

Within these wide objectives and parameters, there will be variations on the structure of the patch and the methods of restoration. Although the non-circular configuration of the sheet material and ring are believed to be critical, the shape of the patch 72 may vary widely to provide the best anatomical fit with the natural shape of the ventricle 25. The sheet material 81 may be composed of a variety of materials, both natural and artificial. These materials may be woven or nonwoven to achieve a desired structure for the sheet material 81. The ring 87 may similarly be formed from a variety of materials and provided with a variety of shapes in order to add structure to the patch 72 without interfering with the normal contractions of the heart 12. Variations of the steps of the associated restoration method might include mounting the patch with a convex surface facing the ventricular cavity, use of tissue adhesives are also contemplated for attaching sealing and otherwise fixing the patch 72 to the Fontan neck 78.

## (57) ABSTRACT

Materials and methods for photoreactive suturing of biological tissue are disclosed. The suture material includes a structure adapted for positioning at an anastomotic site and has at least a portion of the structure formed by a photoreactive crosslinking agent, such that upon irradiation of the structure the crosslinking agent adheres to the biological material. In one embodiment, the suture material can also include a high tensile strength element which is coated with a laser activatable crosslinking agent or glue. The suture methods can be practiced manually, or with various apparatus, such as endoscopes, catheters or hand-held instruments.
